

Population Projections for South Sudan by County by Sex.

From 2008-2015

National Bureau of Statistics,

Juba.

December, 2014

Preface

There has been a lot of demand for population projection and understandably so because it is not appropriate to keep planning with one year figure. For effective managing for results, planners need to know the number of the population segments they are planning for. For that, the Bureau has produced this document. The cohort component method of population projection was used to project the population into the future. This was done by single year and for the period 2008 to 2015. The population was broken down according to the county population distribution of 2008.

It is the hope of the Bureau that the public, especially the planners use this information.

A handwritten signature in black ink, appearing to read 'Isaiah Chol Aruai', with a stylized flourish at the end.

Isaiah Chol Aruai,
Chairperson, NBS

IOM	:	International Organization for Migration
NBS	:	National Bureau of Statistics
SSHHS	:	South Sudan Household Health Survey
SR	:	Sex ratio

1.0 Introduction

Managing for results is an important principle and is an objective for projecting into the future. This calls for population projection to provide what changes might occur given the assumptions inherent in the projection method and the data. There are a number of techniques for population projection. The Bureau decided to use cohort component method. The method uses the components of demographic change to project the population growth. It projects the population by age and sex. Usually the projection is done by age groups and therefore, in five-year groupings. We have decided to conduct projections in single years using the Census 2008 data as base.

As a result of signing the Comprehensive Peace Agreement (CPA) in January, 2005, a number of South Sudanese returned from exile as well as from the then northern Sudan. This was a one-time massive return without associated out-migration. This information was got from International Organization for Migration (IOM). The largest part of this home-coming was between 2008 and 2011. IOM had their records of returnees by county in each state.

The components under consideration are births, deaths and migration. Births and mortality parameters were got from Census 2008 and SSHHS 2010 data. Projection for the years 2009 and 2010 were done using the parameters derived from Census 2008 data. Thereafter, the projections were done using parameters derived from SSHHS 2010 data. Migration data were got from IOM. These were used to move the population to midyear 2008. Thereafter, the population was closed to migration.

2.0 Methodology

The projections given are midyear population distributions. The population of 2008 was moved from April, 2008 to midyear 2008. This was done by estimating number of children that would have been born in the nine weeks to midyear of 2008, the expected deaths in the nine weeks as well as the returnees who would have come in the same period. As stated earlier, the population was then closed to migration in the subsequent projections.

2.1 Moving the population to mid-year 2008

Census was conducted in April, 2008. The Census Night was 21st /22nd April, 2008. This gives nine weeks to middle of the year. The population in each age, P_x was subjected to state level ASMR, $1q_x$, $d_x = P_x \cdot 1q_x$. These are the expected deaths in one year. To get the deaths in 9 weeks from April to end of June, we get the contribution in the 9 weeks, $d_{xa} = d_x \cdot \frac{9}{52}$. This number is subtracted from $P_{x,a}$ to leave only those who would have reached middle of the year.

The births were got by multiplying women in age groups 15-19, 20-24, ---, 45-49 by the state ASFR for women in the age group. $B(i) = W(i) \cdot f(i)$ where $i=1, 2, \dots, 7$.

Where $B(i)$ = Births in age group i
 $W(i)$ = Women in age group i
 $f(i)$ = Age specific fertility rate for women in age group i

The total births was got by summing all births in the seven age groups, $B = \sum_1^7 B(i)$. This is the expected births in one year. To get the births in the 9 weeks to middle of the year, the total births was multiplied by $\frac{9}{52}$, $B_a = B \cdot \frac{9}{52}$. These are broken down into males and females by using the sex ratio, SR=1.03. The results are put at age 0.

Migration data were got from IOM. These were broken down into counties and states and were given as a sum of movements from 2008 to 2011. These were reported as net movement from 2008 to 2011. To use them, the total figure for each state was divided by 4 to distribute them over the four years. This implies that some of these people came before census and, therefore, were enumerated during the census exercise. In all, the number for 2008 was multiplied by $\frac{9}{52}$ to get the contribution from last week of April, 2008 to middle of the year. These were broken down into males and females using sex ratio, SR=1.03. These were then distributed to ages according to the percentage distribution of Census 2008 by sex. These figures were added to the population at midyear, 2008.

As already stated, component method of population projection was used in this assignment and was done by single year. For the total population at age x in April, 2008 $P_{x,a}$ with a specified age specific fertility rate and age specific mortality rates and a given volume of migration, the population at the end of June, 2008 is given by $P_{x,m} = P_{x,a} - D_{x,a} + B_a + NM_{x,a}$. This was done for each sex.

Where

$P_{x,m}$ = Population at end of June, 2008

$P_{x,a}$ = Population in April, 2008

$D_{x,a}$ = Deaths in the nine weeks to midyear of 2008

B_a = Births in the nine weeks to midyear of 2008

$NM_{x,a}$ = Net migration in the nine weeks to midyear of 2008

This then results to the population used in the projection as the midyear 2008 population. Because of the assumed midyear migration population, imbedded in the projection, the population is assumed closed to migration because the massive return was a one-time return.

The base of the projection is the population enumerated in April, 2008. That time, the male population was higher than the female population. The reason for this was many families had their families outside of South Sudan. This is the reason why males are higher than females. But we also note that the sex ratio for the then Sudan was estimated above 101 (UN, 2006).

2.2 Projections into the future

Component method of population projection is used in this assignment. And this is done in single years. For the total population P_t with a specified age specific fertility rate and age specific mortality rates, the population of the state under consideration at time $t+1$ is given by $P_{t+1} = P_t - D_t + B_t$

Where

P_{t+1} = Population one year from base

P_t = The base population

D_t = Deaths in the year

B_t = Births in one year

The component method, therefore, removes the expected number of people who should have died as they move to the next age. It adds by sex the new born at age 0. The population was closed to migration with the assumption that the number of immigrants equals the number of emigrants.

These total populations for the 2008-2015 were distributed according to the state population distribution by county in the Census 2008. The county population distributions for each state are presented in Annex 2. The projected population, both sexes, for each state is presented in Annex 1. These were then broken down by sex according to the sex ratio estimated for that year. The percentage distribution of the population by sex for the period 2008-2015 for each state is presented in Annex 1.
